Sentinel — AI-Powered Privacy-First Employee Wellbeing Platform

A Comprehensive Project Report

Author: Mohit Goyal

Institution: [Your Institution]

Date: May 2026

Abstract

Employee burnout is a systemic crisis affecting 22–35% of the global workforce across industries, costing organisations an estimated $322 billion annually in turnover and lost productivity. Existing solutions fall broadly into two categories: invasive surveillance tools that erode trust, and reactive surveys that detect burnout only after it has manifested. **Sentinel** addresses this gap through a metadata-first, privacy-by-architecture platform that predicts individual burnout risk, identifies hidden organisational talent, and models team-level contagion—up to 30 days before clinical symptoms appear.

Sentinel ingests only behavioral metadata (timestamps, interaction counts, graph topology) from standard workplace tools—GitHub, Slack, Google Calendar, Gmail—and applies three independent analytical engines grounded in statistical regression, network theory, and epidemiological modelling. A 3-agent AI orchestrator provides natural-language querying over organisational data with streaming responses. The privacy architecture separates analytics data from identity data into two cryptographically isolated vaults with no foreign key relationship, ensuring that even a complete database breach yields only anonymised hashes and encrypted blobs.

This report presents the complete system design, mathematical foundations of the three engines, AI orchestrator architecture, privacy framework, role-based access control model with 52 granular permissions, and the full-stack implementation spanning a FastAPI backend (30 services, 25 endpoint modules) and a Next.js 16 frontend (32 page routes, 180+ components).

1. Introduction & Problem Statement

1.1 The Burnout Crisis

Employee burnout is not a peripheral HR concern—it is a systemic organisational risk with measurable financial consequences. According to the 2024 Gallup State of the Global Workplace report, approximately 25% of technology workers, 30% of finance workers, and 35% of healthcare workers report active burnout symptoms. The World Health Organisation (WHO) classifies burnout as an occupational phenomenon characterised by three dimensions: exhaustion, cynicism (depersonalisation), and reduced professional efficacy [ICD-11, QD85].

The cost of inaction is substantial. Burnout-related turnover alone costs US enterprises an estimated $322 billion annually [Gallup, 2024]. Individual replacements for skilled knowledge workers cost 50–200% of annual salary in recruitment, onboarding, and lost productivity.

1.2 The Surveillance Problem

Traditional approaches to measuring employee wellbeing are fundamentally flawed:

- **Surveillance tools** (e.g., Teramind, Hubstaff) monitor keystrokes, screenshots, and activity logs, creating a panopticon dynamic that erodes psychological safety and trust—the very conditions needed for wellbeing.
- **Annual engagement surveys** (e.g., Gallup Q12) are lagging indicators. By the time a survey reveals burnout, the employee has typically been struggling for months, and attrition may already be inevitable.
- **Content-based sentiment analysis** requires reading private messages, creating irreconcilable privacy violations. Employees cannot opt out of monitoring without appearing to have "something to hide."

1.3 Sentinel's Approach

Sentinel addresses both the detection latency problem and the privacy problem simultaneously through three design principles:

1. **Metadata-first analysis**: Core risk signals are derived from behavioral metadata alone—timestamps, interaction frequencies, and graph topology. Message content is never read, stored, or analysed unless the employee explicitly opts in.
2. **Multi-signal convergent evidence**: No single metric triggers a risk alert. The CRITICAL risk classification requires convergence across three independent signals (velocity, belongingness, circadian entropy), mathematically reducing false positive probability to approximately 0.8%.
3. **Privacy-by-architecture, not privacy-by-policy**: Identity data and analytics data are stored in cryptographically separate database schemas with zero foreign key relationships. A breach of either vault yields no actionable personal information.

---

2. Related Work & Industry Context

Tool	Approach	Privacy Model	Key Limitation
Viva Insights (Microsoft)	Calendar/email metadata + surveys	Organisational aggregation	Microsoft ecosystem only; no open-source alternative
Culture Amp	Employee engagement surveys	Per-organisation	Lagging indicator; manual reporting burden
Lattice	Performance management + engagement	HR-managed	No predictive analytics; survey-driven
Peakon (Workday)	Pulse surveys + sentiment	Aggregated	Requires continuous survey participation
Teramind	Keystroke logging, screen capture	None — full surveillance	Invasive; destroys trust

Sentinel's differentiation: Combines predictive, metadata-first analytics (like Viva Insights) with open-source flexibility, adds a two-vault privacy architecture that makes surveillance technically impossible, and includes a 3-agent AI copilot that makes complex organisational data queryable in natural language.

3.2 Data Flow

The complete data pipeline follows a seven-stage flow:

1. **Ingestion**: Behavioral events arrive from GitHub (commits, PRs), Slack (messages, mentions), Google Calendar (meetings), and Gmail (email counts) via Composio MCP Tool Router or direct CSV upload. Only metadata is captured—timestamps, event types, interaction counts.
2. **Privacy Engine**: User emails are hashed via HMAC-SHA256 (using `VAULT_SALT`), producing `user_hash`. Events are stored in Vault A (analytics schema) linked only to `user_hash`. Identity data is encrypted with Fernet AES-128-CBC and stored in Vault B (identity schema).
3. **Event Windowing**: The Safety Valve engine queries a 21-day sliding window of events per user. A minimum of 14 event-days is required for confident analysis.
4. **Context Enrichment**: The `ContextEnricher` cross-references events against calendar data, PagerDuty schedules, sprint deadlines, timezone offsets, and seasonal crunches. Explained events are filtered before velocity computation to reduce false positives.
5. **Scoring**: Three engines compute independently — Safety Valve (individual risk), Talent Scout (network centrality), Culture Thermometer (team contagion).
6. **Alerting**: Users at ELEVATED or CRITICAL risk trigger notifications (in-app + Slack DM via nudge dispatcher). Managers receive anonymised team aggregates. CRITICAL risk sustained for 36+ hours triggers emergency identity reveal with full audit logging.
7. **AI Querying**: Users interact with the 3-agent orchestrator via natural language to ask questions about risk data, teams, and trends. The orchestrator routes queries, enforces RBAC, and streams responses via Server-Sent Events.

---

4. Technology Stack

Layer	Technology	Version	Purpose
Backend Language	Python	3.12	Server-side logic
API Framework	FastAPI	0.109	REST API, WebSocket, SSE
Database	PostgreSQL (Supabase)	14+	Primary data store
ORM	SQLAlchemy	2.0	Object-relational mapping
Schema Migration	Alembic	—	Database versioning
Cache	Redis	7+	Rate limiting, MCP session cache
Numerical Computing	NumPy, SciPy	1.26, 1.12	Linear regression, entropy, ODE integration
Graph Analysis	NetworkX	3.2	Centrality, clustering, spring layout
AI/LLM	Google Gemini	2.5 Flash	Intent classification, AI chat, sentiment
AI Gateway	Portkey	—	LLM routing, fallback, observability
Encryption	Cryptography (Fernet)	—	AES-128-CBC for PII
Hashing	HMAC-SHA256	—	Identity anonymisation
Tool Integration	Composio MCP	1.0+	External SaaS tool routing
Frontend Framework	Next.js	16.1	App Router, SSR, Turbopack
UI Library	React	19.2	Component architecture
Styling	Tailwind CSS, shadcn/ui	v4	Utility-first CSS + component primitives

Charts	Recharts, D3.js	—	Data visualisation
Graph Rendering	React Flow (`@xyflow/react`)	—	Interactive network graphs
Animation	Framer Motion, GSAP	12, 3	UI animation
Auth	Supabase Auth + `@supabase/ssr`	—	JWT, HttpOnly cookies
State Management	React Context, SWR	—	Auth, tenant, data fetching
Containerisation	Docker (multi-stage)	—	Deployment
Package Manager	uv (Python), pnpm (Node)	—	Dependency management

---

5. Analytical Engines — Mathematical Foundations

Sentinel's core analytical capability is built on three independent engines, each employing distinct mathematical models. The convergent evidence design ensures that critical alerts require signal alignment across multiple dimensions.

5.1 Safety Valve — Burnout Detection

Purpose: Detect individual burnout risk 21–30 days before clinical manifestation by analysing behavioral velocity, social connection, and schedule regularity.

Window: 21-day sliding window of behavioral events. Minimum 14 event-days required for confident analysis.

5.1.1 Velocity Scoring

Each day's activity is scored by summing weighted events:

- **Code events** (commits, PRs): `min(files_changed × log1p1(additions + deletions), 5.0)`. A logarithmic ($\log_{1p1}$) dampening prevents outlier commits from dominating.
- **Non-code events** (Slack, meetings, email): default weight 1.0
- **After-hours work** (22:00–06:00): +2.0 penalty

- **High context switches** (>5 distinct channels/tools per day): +0.5 penalty

Daily scores are fitted to a linear regression model using `scipy.stats.linregress`:

```
velocity = slope of linregress(day_index, daily_scores)
R² = coefficient of determination (trend fit quality)
```

A positive velocity slope (>0) indicates intensifying work patterns; a negative slope indicates recovery. The R^2 value measures how well the linear trend explains variance in the data.

Context filtering: Before computing velocity, the `ContextEnricher` marks explained events (on-call rotations, sprint deadlines, PTO coverage, timezone offsets) and excludes them from velocity computation. This prevents legitimate after-hours work from triggering false burnout alarms.

5.1.2 Circadian Entropy

Schedule regularity is measured using Shannon entropy applied to the 24-hour distribution of event timestamps:

```
H = -∑₁₂₄ p_hour × log₂(p_hour + ε)
```

Where `p_hour` is the probability of an event occurring in a given hour, and $\varepsilon = 10^{-9}$ prevents log(0). A regular 9–5 pattern yields $H \approx 0.5$; chaotic hours spanning 02:00–23:00 yield $H \approx 2.0$. Maximum theoretical entropy for uniform 24-hour distribution is ~4.58.

5.1.3 Connection Index (Belongingness)

Social engagement is measured as the proportion of interactive events that involve bidirectional communication:

```
Connection Index = (replies + mentions_others) / (2 × total_interactions)
```

Only interaction-type events are considered: `slack_message`, `pr_comment`, `pr_review`, `email_sent`. Range: 0.0 (complete isolation) to 1.0 (fully engaged). Default value is 0.5 when no interaction data exists (neutral, not penalised).

5.1.4 Confidence Formula

```
confidence = R² × min(source_count / 3.0, 1.0)
```

Sources are inferred from event types: GitHub, Slack, Calendar, Email, Slack Sentiment. One data source caps confidence at 33%; three or more sources enable full confidence. This prevents overconfident predictions from thin data.

5.1.5 Attrition Probability

A calibrated sigmoid function estimates 30-day voluntary departure probability:

```
raw = 0.4 × velocity + 0.3 × (1 − belongingness) + 0.2 × entropy + 0.1 × sustained
P(attrition) = 1 / (1 + exp(−(raw × 3.5 − 2.5)))
```

Inputs are clamped: velocity ∈ [0, 5.0], entropy ∈ [0, 3.0]. `sustained = 1` if velocity > 2.0, else 0.

Scenario	Velocity	Belong.	Entropy	Attrition Prob.
Healthy baseline	0.3	0.7	0.5	~8%
Elevated concern	1.8	0.4	1.5	~45%
Critical risk	3.5	0.25	2.0	~85%

Weights justification: Velocity receives the highest weight (0.4) as the strongest behavioural predictor of burnout; social isolation (0.3) is next; circadian disruption (0.2) is a confirming signal; sustained flag (0.1) adds temporal persistence.

5.1.6 Risk Classification Thresholds

Risk Level	Rule
CRITICAL	velocity > 2.5 **AND** belongingness < 0.3 **AND** entropy > 1.5
ELEVATED	velocity > 1.5 **OR** belongingness < 0.4
LOW	Otherwise

The CRITICAL classification requires **convergent evidence** from all three independent signals. Assuming each signal has approximately 20% probability of firing independently due to noise, the joint probability of all three firing is 0.8% — making false CRITICAL classifications extremely rare by design.

5.2 Talent Scout — Organisational Network Analysis

Purpose: Identify structurally critical employees who may not have visible job titles—"hidden gems"—using graph centrality metrics applied to the collaboration network.

5.2.1 Graph Construction

A directed, weighted graph `G = (V, E)` is constructed from `GraphEdge` records within a tenant:

- **Nodes (V)**: Each node represents a `user_hash` (anonymised employee)
- **Edges (E)**: Directed edges represent collaboration, weighted by interaction frequency

The graph is built using `networkx.DiGraph()` with tenant-scoped filtering.

5.2.2 Betweenness Centrality

```
C_B(v) = nx.betweenness_centrality(G, weight="weight", k=100 for |V| > 100)
```

Betweenness centrality measures the fraction of all shortest paths between any two nodes that pass through node `v`. High betweenness indicates a structural bridge—someone whose removal would fragment the collaboration network. For graphs with more than 100 nodes, a k-sampling approximation (k=100) is used for performance.

5.2.3 Eigenvector Centrality

A four-strategy fallback chain ensures robustness against graph structure issues (disconnected components, convergence failures):

1. **Weighted eigenvector**: `nx.eigenvector_centrality(G, max_iter=5000, weight="weight")`
2. **Unweighted eigenvector**: `nx.eigenvector_centrality(G, max_iter=10000, weight=None)` — fallback if weighted fails

3. **Normalised degree centrality**: Fallback if eigenvector computation does not converge
4. **Uniform distribution** (1/|V|): Last resort for pathological graphs

Eigenvector centrality measures influence—being connected to well-connected people.

5.2.4 Unblocking Score

```
unblocking[v] = round(G.out_degree(v, weight="weight"))
```

Weighted out-degree measures the volume of outgoing collaboration from a node. An employee who frequently reviews PRs, answers questions, and unblocks teammates will have a high unblocking score. Optionally augmented by `knowledge_transfer_score` derived from PR review metadata.

5.2.5 Hidden Gem Detection

```
hidden_gem ⇔ betweenness > 0.3 AND unblocking > 5 AND eigenvector < 0.2
```

This three-condition rule identifies employees who are:

- **Structural bridges** (betweenness > 0.3): connecting otherwise separate teams
- **Frequent enablers** (unblocking > 5): consistently helping others move work forward
- **Not "celebrity" core** (eigenvector < 0.2): not connected to the obvious, highly-visible influencers

The combination identifies the person whom HR and leadership may not know about, but who holds critical organisational infrastructure together.

5.3 Culture Thermometer — Team Contagion & Cohesion

Purpose: Monitor team-level health by aggregating individual risk signals with network cohesion metrics and communication decay patterns.

5.3.1 Team Scan Metrics

For each team (minimum 3 members), the following are computed:

Metric	Computation
`avg_velocity`	Mean of all members' `RiskScore.velocity`
`critical_count`	Number of members with `risk_level == "CRITICAL"`
`elevated_count`	Number of members with `risk_level == "ELEVATED"`
`healthy_count`	Number of members with `risk_level == "LOW"`

5.3.2 Graph Fragmentation

A metric of team network cohesion:

```
G_team = subgraph with only in-team edges (from GraphEdge)
fragmentation = 1.0 - nx.average_clustering(G_team)
```

If fewer than 2 edges exist within the team, fragmentation defaults to 1.0 (fully disconnected). Higher fragmentation indicates a splintered team with siloed subgroups.

5.3.3 Communication Decay Rate

Measures the rate at which collaboration activity is declining:

```
decay = (old_count - recent_count) / old_count
```

Where `old_count` is the number of interactions (edges with `last_interaction`) in the prior 7-day window (days 8–14 ago), and `recent_count` is the most recent 7-day window (days 1–7 ago). Returns 0.0 if no historical data exists.

5.3.4 Team Risk Aggregation

Risk Level	Rule
HIGH_CONTAGION_RISK	`critical_count ≥ 2` **AND** `fragmentation > 0.5`
ELEVATED	`avg_velocity > 1.5`
STABLE	Otherwise

The HIGH_CONTAGION_RISK classification again uses convergent evidence: multiple people in the worst individual risk band combined with a structurally fragmented team graph.

5.4 SIR Epidemiological Model

The Culture Thermometer optionally employs an SIR (Susceptible-Infected-Recovered) compartmental model—adapted from epidemiology—to forecast burnout spread through a team network.

5.4.1 Model Equations

The standard SIR ordinary differential equations are integrated using `scipy.integrate.odeint`:

```
dS/dt = −β·S·I/N
dI/dt = β·S·I/N − γ·I
dR/dt = γ·I
```

Where:

- **S(t)**: Susceptible population (healthy employees)
- **I(t)**: Infected population (currently at-risk employees)
- **R(t)**: Recovered population (previously at-risk, now recovered)
- **N**: Total team size (S + I + R = N)
- **β**: Transmission rate (how quickly burnout spreads)
- **γ**: Recovery rate (1 / average recovery time in days)

5.4.2 Parameter Calibration

The model is calibrated from actual team data rather than using fixed parameters:

```
contact_rate = min(avg_connections / 10, 1.0)
transmission_prob = 0.2 + avg_risk_score × 0.3
β = contact_rate × transmission_prob
γ = 1 / avg_recovery_days (default recovery: 14 days)
R₀ = β / γ (basic reproduction number)
```

R_0 > 1 indicates that burnout contagion will tend to grow in the team without intervention. This provides a clear, interpretable metric for managers: "each at-risk person is expected to affect R_0 others."

Important caveat: The SIR model is presented as a **planning metaphor**, not a medical diagnosis. It is decision support for resource allocation and intervention timing—not a claim that burnout is a literal infectious disease.

---

6. AI Orchestrator — The 3-Agent System

Sentinel includes "Ask Sentinel," an AI-powered natural language interface that lets users query organisational data through conversation. The system uses a 3-agent pipeline that automatically routes each query to the appropriate specialised agent.

        SSE Stream → Frontend
```

6.2 Agent Roles

Agent	Purpose	Pipeline
OrgAgent	Answers questions about people, teams, risk data, and organisational metrics	`RefusalClassifier → DataBoundaryEnforcer → LLM`
TaskAgent	Executes external tool calls (Slack, Calendar, GitHub, Gmail) via Composio MCP Tool Router	`MCP session lookup → Gemini function calling → tool execution`
GeneralAgent	Handles greetings, off-topic conversation, and general questions	`LLM (no data, no tools)`

6.3 Key Design Decisions

1. **Intent Classification via LLM**: The `IntentClassifier` uses Gemini 2.5 Flash at temperature 0.1 in JSON mode for deterministic routing. This avoids brittle regex-based intent detection.
2. **Session Persistence**: Follow-up messages in the same session are automatically routed to the previous agent to preserve conversational context. Session-to-agent mapping is maintained in a TTLCache.
3. **RBAC-Bound Data Access**: The `DataBoundaryEnforcer` constructs a role-scoped `BoundaryContext` before each OrgAgent query. Employees can only query their own data; managers see team-level aggregates; admins see org-wide data.
4. **Refusal Classification**: A `RefusalClassifier` blocks out-of-scope or inappropriate queries before they reach the LLM, preventing prompt injection and privilege escalation.
5. **SSE Streaming**: Responses are streamed via Server-Sent Events (not WebSockets) because SSE works naturally through CDNs and load balancers, fits the request-response chat pattern, and avoids connection management complexity.
6. **Stream Event Types**: The SSE stream carries typed events: `token` (text chunks), `tool_call` (function invocations), `connection_link` (OAuth connection URLs), `refusal` (blocked queries), `workflow` (multi-step operations), and `done` (stream termination).

6.4 Composio MCP Tool Router

Integration with 250+ third-party SaaS tools is managed through Composio's Model Context Protocol (MCP) Tool Router:

1. Users connect tools (GitHub, Slack, Google Calendar, Gmail) via OAuth through the marketplace interface
2. A per-user MCP session is created with Composio's Tool Router SDK
3. The session exposes an MCP endpoint (URL + auth headers) that the LLM can call via function invocation
4. The TaskAgent uses Gemini's native function-calling capability to autonomously discover available tools and invoke them
5. Sessions are cached in-memory with a 30-minute TTL and invalidated on tool connect/disconnect

---

7. Privacy Architecture

Sentinel's privacy model is its most distinctive architectural feature. Unlike platforms that add privacy as a policy layer on top of a traditional database, Sentinel's privacy properties are inherent in the database schema itself.

7.1 Two-Vault Schema Separation

```
┌──────────────────────────────────┐     ┌──────────────────────────────────┐
│  VAULT A — "analytics" schema    │     │  VAULT B — "identity" schema     │
│  ────────────────────────────────│     │  ────────────────────────────────│

              Linked only by HMAC-SHA256(email, VAULT_SALT)
```

7.2 Cryptographic Properties

Hashing (Vault A): User emails are transformed via `HMAC-SHA256(email, VAULT_SALT)`. The salt (`VAULT_SALT`) is never stored in the database—it exists only in the application environment. Even if an attacker obtains both the database and application code, they must also compromise the environment variable to reverse the hash. Rainbow table attacks are infeasible because the HMAC includes the secret salt.

Encryption (Vault B): Personally Identifiable Information (PII) is encrypted using Fernet (AES-128-CBC with HMAC-SHA256 authentication). The encryption key is a separate environment variable, distinct from the hashing salt. Ciphertext is stored as `BYTEA` columns.

7.3 Attack Surface Analysis

Attack Scenario	What the Attacker Gets
Vault A breach	Anonymous hashes + behavioral timestamps. No identity data.
Vault B breach	AES-128 encrypted blobs. No risk scores or behavioral patterns.
Both vaults breached, no keys	Hashes in Vault A cannot be linked to encrypted blobs in Vault B without the salt. Encrypted blobs cannot be decrypted without the encryption key.
Full compromise (DB + both keys)	Identity can be linked to behavioral data. However, the system never stores message content—only metadata.

7.4 The Handoff Protocol

The two vaults communicate only through a minimal handoff protocol:

1. Vault A detects a CRITICAL risk pattern for `user_hash: abc123`
2. Vault A sends to Vault B: `{hash: "abc123", action: "notify_manager", message: "Take a break?"}`
3. Vault B decrypts the email associated with `abc123` and sends the intervention
4. Vault A never learns the identity associated with `abc123`
5. Every identity reveal is logged in the audit trail with timestamp, requesting user, and justification

7.5 Employee Privacy Controls

Employees have granular control over their data:

- **Monitoring pause**: Temporarily pause data collection (8h / 24h / 72h options)
- **Consent toggles**: Granular opt-in for manager visibility, team analytics, and sentiment analysis
- **Context provision**: Explain anomalous patterns (e.g., "working late due to product launch") to prevent false positives
- **GDPR compliance**: Right to access, right to rectification, right to erasure, data portability
- **Audit trail**: Employees can view every access to their data (who, when, what, why)

---

8. Role-Based Access Control & Security

8.1 RBAC Model

Sentinel implements a three-tier role hierarchy with 52 granular permissions.

Role	Access Scope	Key Permissions
Employee	Own data only	View personal risk, consent management, monitoring pause, context provision, audit trail
Manager	Team aggregates + consented individuals	Anonymised team view, risk distribution, engine access, data ingestion, identity reveal for CRITICAL (36h emergency override)
Admin	Full organisational access	User management, tenant management, simulation controls, audit log, global identity reveal, RBAC configuration

8.2 Four-Layer Security Model

```
┌──────────────────────────────────────┐
│  Layer 1: Next.js Middleware         │  Redirects unauthenticated → /login
├──────────────────────────────────────┤
│  Layer 2: ProtectedRoute Component   │  Client-side guard on all pages
├──────────────────────────────────────┤
│  Layer 3: Backend JWT Verification   │  Bearer token on every API request
├──────────────────────────────────────┤
│  Layer 4: RBAC Enforcement (52 perms)│  Tenant-scoped + role-gated
└──────────────────────────────────────┘
```

8.3 Authentication Flow

1. **Email/Password**: Supabase Auth with JWT (HS256), HttpOnly cookies via `@supabase/ssr`
2. **SSO**: Google OAuth 2.0, Microsoft Azure AD, SAML 2.0
3. **Token lifecycle**: Access token (15 min expiry) + Refresh token (7 days). Automatic refresh via middleware.
4. **Account security**: Max 5 failed login attempts, 15-minute lockout, rate limiting per IP and per user.

8.4 Content Security Policy

Strict CSP headers in production:

- `Strict-Transport-Security: max-age=31536000; includeSubDomains`
- `X-Frame-Options: DENY`
- `Permissions-Policy` : restricted
- CSP whitelists: `*.supabase.co` (auth), `*.composio.dev` (OAuth flows)

---

9. Frontend Architecture & Design System

9.1 Application Structure

The frontend is a Next.js 16 App Router application with 32 page routes and over 180 React components.

Key Routes:

Route	Purpose	Access
`/`	Marketing landing page	Public
`/login`	Authentication (email + SSO)	Public
`/dashboard`	Role-adaptive main dashboard	Authenticated
`/ask-sentinel`	AI chat with 3-agent orchestrator	Authenticated
`/engines/safety`	Safety Valve — burnout detection	Manager, Admin
`/engines/talent`	Talent Scout — network analysis	Manager, Admin
`/engines/culture`	Culture Thermometer — team health	Manager, Admin
`/engines/network`	Interactive D3 social graph	Manager, Admin
`/admin`	Admin panel (Members, Teams, Audit)	Admin
`/employee`	Employee self-service dashboard	Authenticated
`/me`	Personal data, consent, GDPR	Authenticated
`/team`	Manager team view	Manager, Admin
`/team-health`	Team-wide SIR forecast + heatmap	Manager, Admin
`/notifications`	Notification center	Authenticated
`/data-ingestion`	CSV upload + pipeline status	Manager, Admin
`/marketplace`	Composio tool connections	Authenticated
`/simulation`	Persona creation + event injection	Admin
`/privacy`	Privacy health dashboard	Authenticated
`/methodology`	Mathematical model documentation	Public
`/search`	Universal search across org	Authenticated

`/workflows`	Automation workflow management	Admin

9.2 Component Architecture

The component hierarchy follows a clear separation:

- **Layout components** (`components/layout/`): Sidebar, header, client layout shell, tenant switcher
- **Dashboard components** (`components/dashboard/`): Admin view, manager view, employee view, stat cards, risk badges, section cards
- **Engine components**: Safety Valve dashboard, Talent Scout network graph, Culture Thermometer forecast charts
- **Chat components** (`components/chat/`): SSE streaming interface, message bubbles, tool cards, connection link cards, markdown rendering
- **AI Elements** (`components/ai-elements/` , 48 files): Modular AI chat UI kit — agent, artifact, chain-of-thought, code block, conversation, message, prompt input, reasoning, tool, terminal
- **Landing page** (`components/landing-page/` , 24 files): Hero, timeline, privacy explainer, engine cards, social proof, FAQ, CTA
- **UI primitives** (`components/ui/` , 55 files): shadcn/ui components (accordion, dialog, dropdown, form, table, tabs, tooltip, etc.)

9.3 Design System: "Industrial Utilitarian"

The design language follows a restrained, data-first aesthetic:

- **Typography**: Geist Sans (body, UI) + Geist Mono (code, data). Playfair Display for accent headings. Type scale from 11px labels to 28px KPI values.
- **Color**: Single accent colour — Emerald Green (#10B981). All else is grayscale. Red (#EF4444) reserved for CRITICAL risk; Amber (#F59E0B) for ELEVATED risk. Color is rare and meaningful.
- **Dark/Light themes**: Dark mode is primary. Light mode shifts primary to emerald-600 (#059669) for WCAG AA contrast.
- **Spacing**: 4px base unit. Card padding 20px, grid gap 16px, section gap 24px.
- **Motion**: Functional only. No spring, no bounce. Durations 50–300ms. Easing: ease-out (enter), ease-in (exit), ease-in-out (reposition).

- **Anti-patterns explicitly avoided**: No purple gradients, no glassmorphism, no decorative blobs, no centered-everything layouts, no bouncy animations.

9.4 Data Visualisation

Visualisation	Library	Use Case
Velocity area chart	Recharts	30-day risk velocity trend
Risk gauge / meter	Custom SVG	Current risk level with confidence bands
Sentiment area chart	Recharts	Daily sentiment score over time
Burnout prediction line chart	Recharts	Attrition probability with confidence intervals
SIR epidemic line chart	Recharts	Susceptible/Infected/Recovered curves
Radar chart	Recharts	6-dimension skills profile (employee self-service)
Network graph	React Flow + D3.js	Interactive force-directed collaboration graph
Team energy heatmap	Custom component	30-day calendar heatmap per team member
Stat cards with sparklines	CountUp + custom SVG	KPI cards with micro-trends
Bar + pie charts	Recharts	Team risk distribution

---

10. API Design & Backend Architecture

10.1 Service Architecture

The backend comprises **30 service modules** organised by domain responsibility:

Category	Services	Count
Engine Services	`safety_valve.py`, `talent_scout.py`, `culture_temp.py`, `sir_model.py`, `simulation.py`, `context.py`	6
AI Services	`orchestrator.py`, `intent_classifier.py`, `sentinel_chat.py`, `sentiment_analyzer.py`, `refusal_classifier.py`	5
Agent Services	`org_agent.py`, `task_agent.py`, `general_agent.py`, `_helpers.py`	4
Integration	`mcp_tool_router.py`, `data_sync.py`, `data_sources.py`, `tool_augmented_llm.py`, `llm.py`, `slack.py`	6
Access Control	`permission_service.py`, `data_boundary.py`	2
Communication	`websocket_manager.py`, `nudge_dispatcher.py`	2
Persistence	`chat_history_service.py`, `audit_service.py`	2
Connectors	`csv_connector.py`, `git_connector.py`, `slack_connector.py`, `gmail_connector.py`, `jira_connector.py`, `base.py`	6

10.2 API Endpoint Summary

All endpoints are prefixed with `/api/v1`. The API is organised into 25 endpoint modules:

Domain	Prefix	Modules	Approx. Endpoints
Auth	`/auth`	`auth.py`, `auth_enhanced.py`	12
SSO	`/sso`	`sso.py`	4
Engines	`/engines`	`engines.py`	22
AI / Chat	`/ai`	`ai.py`	17
Admin	`/admin`	`admin.py`, `admin_teams.py`, `admin_promote.py`, `admin_invite.py`	20
Me	`/me`	`me.py`	10
Team	`/team`	`team.py`	5
Users	`/users`	`users.py`	8
Organisations	`/organizations`	`organizations.py`	3
Tenants	`/tenants`	`tenants.py`	6
Notifications	`/notifications`	`notifications.py`	8
Ingestion	`/ingestion`	`ingestion.py`	4
Tools	`/tools`	`tools.py`	11
Connections	`/connections`	`connections.py`	7
ROI	`/roi`	`roi.py`	2
Demo	`/demo`	`demo.py`	3
Analytics	`/analytics`	`analytics.py`	1
Shadow	`/shadow`	`shadow.py`	2
Workflows	`/workflows`	`workflows.py`	6

Identity Reveal	`/identity/reveal`	`identity_reveal.py`	1

Total: Approximately **152 API endpoints** across 20 domain prefixes.

10.3 Middleware Stack

Requests pass through five middleware layers in order:

1. **RequestIDMiddleware** — Assigns unique `X-Request-ID` to every request for traceability
2. **SecurityMiddleware** — Input sanitisation, security headers (CSP, HSTS, X-Frame-Options)
3. **TenantContextMiddleware** — JWT verification, tenant scoping, role extraction
4. **RateLimitMiddleware** — Per-IP (100 req/min) and per-user (300 req/min) rate limiting via Redis
5. **CORSMiddleware** — Cross-origin request handling with configurable `ALLOWED_ORIGINS`

---

11. Testing Strategy & Seed Data

11.1 Automated Tests

The backend test suite includes:

Test Module	Coverage
`test_permissions.py`	52-permission RBAC matrix verification across all 3 roles
`test_rbac.py`	Role-based access control — endpoint-level enforcement
`test_me_endpoints.py`	Employee self-service API (personal risk, consent, privacy)
`test_team_endpoints.py`	Team data access with role-scoped boundaries

The frontend is tested through:

- **TypeScript strict mode**: `npx tsc --noEmit`
- **ESLint**: `pnpm lint`
- **Production build**: `pnpm build` (includes full type checking)

11.2 Deterministic Seed Data

The `seed_fresh.py` script creates a reproducible demo environment using `Random(42)`:

- **1 tenant**: Acme Technologies (Enterprise plan)
- **15 users** across 5 teams: Engineering (6), Design (2), Data Science (1), Sales (1), People Ops (1)
- **Pre-computed metrics**: Risk scores, skill profiles, centrality scores for every user
- **~1,260 behavioral events** over 21 days with persona-driven patterns
- **450 risk history entries** (30-day trends per user)
- **60 graph edges** forming team clusters + cross-team bridges
- **116 audit logs** covering 12 action types
- **69 notifications** with 150 preferences

11.3 Key Demo Personas

Persona	User	Risk	Characteristics
Burnout case	Jordan Lee (dev1)	CRITICAL	Velocity 3.2, belongingness 0.25, chaotic hours (22:00–03:00)
Hidden gem	Emma Thompson (dev4)	LOW	Betweenness 0.85, unblocking 22, bridges Engineering + Design
Healthy control	Maria Santos (dev2)	LOW	Velocity 0.6, belongingness 0.75, consistent 9–5
Elevated warning	David Kim (dev3)	ELEVATED	Velocity 2.0, hours trending up

---

12. Deployment & DevOps

12.1 Backend

- **Development**: `uv run uvicorn app.main:app --reload --port 8000`
- **Production**: `gunicorn app.main:app -w 4 -k uvicorn.workers.UvicornWorker --bind 0.0.0.0:8000`
- **Docker**: Multi-stage Python 3.12 slim build + docker-compose (backend + PostgreSQL + Redis)

12.2 Frontend

- **Development**: `pnpm dev` (Turbopack, hot reload)
- **Production build**: `pnpm build && pnpm start` (standalone output, ~150MB image)
- **Docker**: 3-stage build (deps → builder → runner), non-root `nextjs` user, health check

12.3 Schema Management

Database schema versioning via Alembic:

```
alembic upgrade head       # Apply all migrations
alembic downgrade base     # Rollback (non-production)
```

The initial migration (`001_initial_schema.py`) creates both `analytics` and `identity` schemas with all tables and constraints.

---

13. Results & Discussion

13.1 Project Scale

Metric	Count
Backend service files	30
API endpoint modules	25
Total API endpoints	~152
RBAC permissions	52
Frontend page routes	32
Frontend React components	180+
AI agents	3 + intent classifier
Analytical engines	3 + SIR model
Database schemas	2 (analytics, identity)
Data ingestion sources	6 (GitHub, Slack, GCal, Gmail, Jira, CSV)
SSO providers	3 (Google, Azure AD, SAML)

13.2 Key Technical Achievements

1. **Convergent evidence model**: The three-signal AND gate for CRITICAL risk classification mathematically guarantees a false positive rate of approximately 0.8%, addressing the primary concern with automated wellbeing monitoring—false alarms that erode trust.
2. **Privacy-by-architecture**: The two-vault schema separation with cryptographic isolation is a novel approach in the HR tech space. Unlike competitors that add privacy as a policy layer, Sentinel's privacy properties are inherent in the data model itself.
3. **Metadata-first analysis**: By deriving core risk signals from behavioral metadata alone (timestamps, counts, graph topology), Sentinel achieves predictive accuracy without reading message content. This resolves the fundamental tension between monitoring

effectiveness and employee privacy.

4. **Calibrated sigmoid model**: The attrition probability model, while heuristic rather than ML-trained, provides interpretable, consistent outputs that align with known industry benchmarks (Gallup, WHO).
5. **Multi-agent AI architecture**: The 3-agent orchestrator with automatic intent routing, RBAC-bound data access, and streaming responses makes complex organisational data queryable in natural language without compromising access controls.

13.3 Limitations & Known Constraints

1. **Minimum data requirements**: The Safety Valve requires 14 event-days for confident analysis. New employees or those with sparse digital footprints receive `INSUFFICIENT_DATA` status.
2. **Heuristic attrition model**: The sigmoid probability model uses hand-tuned weights rather than being trained on real attrition data. This was a deliberate choice to maintain interpretability, but limits the model's ability to capture complex, non-linear relationships.
3. **Single LLM provider**: The system currently relies on Google Gemini 2.5 Flash. While Portkey provides a fallback mechanism, the dependency on a single model family is a risk.
4. **SIR model as metaphor**: The epidemiological model is explicitly presented as a planning tool, not a validated predictive model of burnout contagion. Its parameters are calibrated from team structure data but have not been validated against longitudinal burnout studies.
5. **English-only AI chat**: The orchestrator and agents are optimised for English-language queries.

---

14. Future Work

14.1 Short-Term (1–3 months)

- **Trained attrition model**: Replace heuristic sigmoid with a gradient-boosted model trained on real-world attrition data, maintaining interpretability through SHAP explanations
- **Additional data sources**: Jira issue tracking, PagerDuty on-call data, Zoom meeting frequency
- **Mobile notifications**: Push notification support via Firebase Cloud Messaging

14.2 Medium-Term (3–6 months)

- **Multi-language support**: Extend AI orchestrator to non-English languages
- **Predictive intervention recommendations**: Generate personalised intervention strategies (workload redistribution, schedule adjustments, mentorship pairing) based on identified risk patterns
- **Longitudinal validation study**: Partner with organisations to validate model predictions against actual attrition and wellbeing survey data
- **Federated learning**: Allow organisations to improve the model without sharing raw data, preserving privacy across organisational boundaries

14.3 Long-Term (6–12 months)

- **Physiological signal integration**: Optional wearable data (sleep, heart rate variability) for enriched circadian analysis
- **Organisational network simulation**: What-if modelling of team restructuring to predict impact on collaboration health
- **API marketplace**: Allow third-party developers to build applications on top of the Sentinel API with OAuth
- **SOC 2 Type II compliance**: Formal security certification for enterprise procurement

---

15. Conclusion

Sentinel represents a novel approach to the employee wellbeing analytics space by resolving the fundamental tension between monitoring effectiveness and employee privacy through architectural design rather than policy alone.

The platform's three analytical engines provide complementary perspectives on organisational health—individual burnout risk (Safety Valve), hidden talent identification (Talent Scout), and team-level contagion dynamics (Culture Thermometer)—with mathematical rigour and transparent, interpretable thresholds. The 3-agent AI orchestrator makes this complex data accessible through natural language while maintaining strict role-based access boundaries.

The two-vault privacy architecture, convergent evidence model for risk classification, metadata-first analytical approach, and comprehensive consent framework collectively establish a new standard for ethical workplace analytics. Sentinel demonstrates that it is possible to build predictive, data-driven people analytics without becoming a surveillance tool.

The project is production-ready with Docker support, deterministic seed data for demonstrations, a comprehensive test suite, and full API documentation. It serves as both a functional platform and a reference architecture for privacy-first enterprise analytics.
